```
        ]
~ $ aws dynamodb get-item \
>   --table-name ContentCatalog \
>   --key '{"Id":{"N":"202"}}' \
>   --projection-expression "Title, ContentType, Services" \
>   --return-consumed-capacity TOTAL
{
  "Item": {
    "Title": {
      "S": "Don't miss out!"
    },
    "ContentType": {
      "S": "Video"
    }
  },
  "ConsumedCapacity": {
    "TableName": "ContentCatalog",
    "CapacityUnits": 0.5
  }
}
~ $ |
```

# Introducing Today's Project!

## What is Amazon DynamoDB?

Amazon DynamoDB is a managed NoSQL database service that offers fast, scalable, and highly available storage. It helps applications handle low-latency data access, automatic scaling, and flexible storage without complex infrastructure management.

## How I used Amazon DynamoDB in this project

In today's project, I used Amazon DynamoDB to query and retrieve data efficiently. I executed AWS CLI commands to fetch specific attributes, handled related data across tables, ran transactions for consistency, and explored query options to optimize.

## One thing I didn't expect in this project was...

One unexpected part of this project was how flexible DynamoDB queries are. Using ProjectionExpression and ConsistentRead made data retrieval more efficient than expected, simplifying complex queries.

## This project took me...

This project took less than 35 minutes, thanks to previous experience and the insights gained along the way. It was efficient and informative, making the learning process smooth and rewarding.

# Querying DynamoDB Tables

A partition key is the primary filter DynamoDB uses to separate and locate data efficiently. It doesn't require uniqueness multiple items can share the same value, like "Blue" or "Green." However, in this table, each item has a unique partition key,

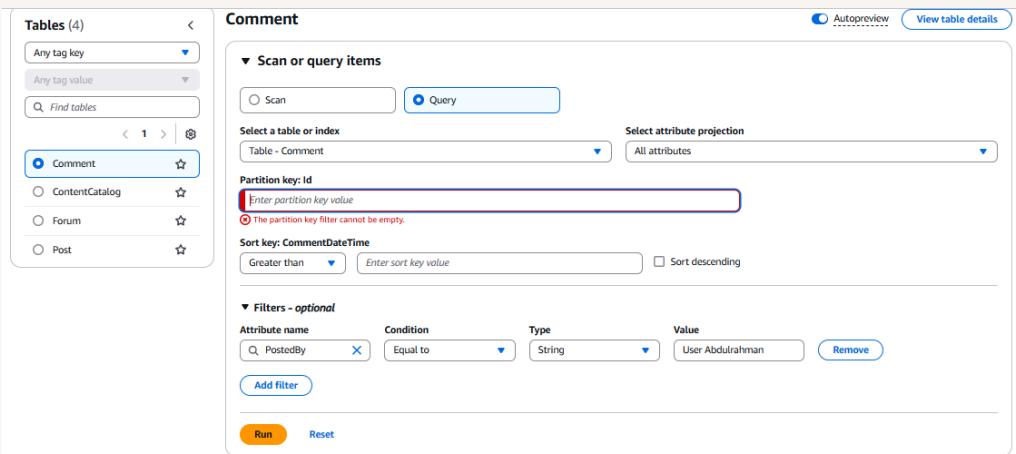

A sort key is a secondary key in DynamoDB that refines queries after the partition key. It's optional but useful when multiple items share a partition key, creating a unique primary key for structured data management and efficient searches.

Table: Comment - Items returned (1)				
Query started on May 08, 2025, 12:25:48				
	Id (String)	CommentDateTime (String)	Message	PostedBy
<input type="checkbox"/>	I have a question/Just...	2024-09-01T19:58:22.947Z	Legendary	User Abhishek

# Limits of Using DynamoDB

The error occurred because DynamoDB requires a partition key in queries. Filters refine results but don't replace the need for it, as the partition key determines where data is stored and retrieved. Without it, DynamoDB can't locate the relevant item

Insights we could extract from our Comment table include user feedback, timestamps, and comment trends. Insights we can't easily extract include sentiment analysis, comment context, and user interaction patterns.

# Running Queries with CLI

A query I ran in CloudShell was `aws dynamodb get-item --table-name ContentCatalog --key '{"Id":{"N":"202"}}' --projection-expression "Title, ContentType, Services" --return-consumed-capacity TOTAL`. This query retrieves specific attributes.

Query options I could add are ProjectionExpression to limit returned attributes, ReturnConsumedCapacity to track resource usage, and ConsistentRead to ensure the latest data. These options optimize efficiency and accuracy in DynamoDB queries.

```
~ $ aws dynamodb get-item \
>   --table-name ContentCatalog \
>   --key '{"Id":{"N":"202"}}' \
>   --projection-expression "Title, ContentType, Services" \
>   --return-consumed-capacity TOTAL
{
  "Item": {
    "Title": {
      "S": "Don't miss out!"
    },
    "ContentType": {
      "S": "Video"
    }
  },
  "ConsumedCapacity": {
    "TableName": "ContentCatalog",
    "CapacityUnits": 0.5
  }
}
~ $ █
```

# Transactions

A transaction is a set of operations executed as a single unit, ensuring consistency. It follows ACID principles: Atomicity, Consistency, Isolation, and Durability. The table likely shows structured data on transactions, listing attributes like times

I ran a transaction using aws dynamodb get-item --table-name Forum --key '{"Name": {"S": "Events"} }'. This transaction did two things: it retrieved an item from the Forum table using the Name attribute and returned its stored values.

```
~ $ aws dynamodb get-item \
>   --table-name ContentCatalog \
>   --key '{"Id":{"N":"101"}}' \
>   --consistent-read \
>   --projection-expression "Title, ContentType, Services" \
>   --return-consumed-capacity TOTAL
{
  "ConsumedCapacity": {
    "TableName": "ContentCatalog",
    "CapacityUnits": 1.0
  }
}
~ $ aws dynamodb get-item \
>   --table-name ContentCatalog \
>   --key '{"Id":{"N":"202"}}' \
>   --projection-expression "Title, ContentType, Services" \
>   --return-consumed-capacity TOTAL
{
```
